# $2^{\text {nd }}$ Nordic Chemistry Olympiad 

## Theoretical Problems

$4^{\text {th }}$ July 2017<br>Stockholm, Sweden

## Instructions

- Write your name and country code on all pages.
- The test booklet consists of 7 tasks and 40 pages.
- You have 4 hours for the examination. Do not start until the "START" signal is given.
- Use only the ballpoint pen and the calculator that have been handed out.
- Read the entire task before you begin to solve it, as there may be important information at the end of the text that you need to use to solve the task.
- All results must be written within the boxes. Answers written outside the boxes will not be reviewed and corrected. If you need paper, use the back of the paper sheets.
- Show your calculations in the boxes. You will only get max points if you show your calculations.
- When you have finished the exam, you must pass the test booklet to the person in charge.
- You must stop writing when the "STOP" signal is given.
- Stay in your place until you are allowed to leave the room.

## Constants and Formulae

Avogadro's constant, $N_{\mathrm{A}}=6.0221 \times 10^{23} \mathrm{~mol}^{-1}$
Boltzmann constant, $\mathrm{kB}=1.3807 \times 10^{-23} \mathrm{~J} \mathrm{~K}^{-1}$
Universal gas constant, $R=8.3145 \mathrm{~J} \mathrm{~K}^{-1} \mathrm{~mol}^{-1}=0.08205 \mathrm{~atm} \mathrm{~L} \mathrm{~K}{ }^{-1} \mathrm{~mol}^{-1}$
Speed of light, $c=2.9979 \times 10^{8} \mathrm{~m} \mathrm{~s}^{-1}$
Planck's constant, $h=6.6261 \times 10^{-34} \mathrm{~J} \mathrm{~s}$
Faraday constant, $F=9.64853399 \times 10^{4} \mathrm{C}$
Mass of electron, $m_{e}=9.10938215 \times 10^{-31} \mathrm{~kg}$
Standard pressure, $P=1 \mathrm{bar}=10^{5} \mathrm{~Pa}$
Atmospheric pressure, $P_{\mathrm{atm}}=1.01325 \times 10^{5} \mathrm{~Pa}=760 \mathrm{mmHg}=760$ torr
Zero of the Celsius scale, 273.15 K
1 picometer $(\mathrm{pm})=10^{-12} \mathrm{~m} ; \quad 1 \AA=10^{-10} \mathrm{~m} ; \quad$ nanometer $(\mathrm{nm})=10^{-9} \mathrm{~m}$
$1 \mathrm{eV}=1.6 \times 10^{-19} \mathrm{~J}$
$1 \mathrm{amu}=1.66053904 \times 10^{-27} \mathrm{~kg}$
Ideal gas equation: $P V=n R T$
Enthalpy:

$$
H=U-P V
$$

Gibbs free energy: $G=H-T S$

$$
\Delta G=\Delta G^{o}+R T \ln Q
$$

$$
\Delta G^{o}=-R T \ln K=-n F E_{\text {cell }}^{o}
$$

Entropy change: $\quad \Delta S=\frac{q_{r e v}}{T}$, where $q_{r e v}$ is heat for the reversible process

$$
\Delta S=n R \ln \frac{V_{2}}{V_{1}} \text { (for isothermal expansion of an ideal gas) }
$$

Nernst equation: $\quad E=E^{o}+\frac{R T}{n F} \ln \frac{C_{o x}}{C_{r e d}}$
Energy of a photon: $\quad E=\frac{h c}{\lambda}$
Lambert-Beer law: $A=\log \frac{I_{0}}{I}=\varepsilon b C$

Integrated rate law
Zero order

$$
[\mathrm{A}]=[\mathrm{A}]_{0}-k t
$$

First order $\ln [\mathrm{A}]=\ln [\mathrm{A}]_{0}-k t$
Second order $\quad \frac{1}{[\mathrm{~A}]}=\frac{1}{[\mathrm{~A}]_{0}}+k t$
Arrhenius equation

$$
k=A e^{-E_{a} / R T}
$$

Periodic table of the elements with relative atomic masses and electronegativities

## Problem 1

## 8 \% of total

| a | b | c | d | e | f | Problem 1 | $\%$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 10 | 10 | 10 | 10 | 10 | 10 | 60 | 8 |
|  |  |  |  |  |  |  |  |

Salt of hartshorn, used for baking cookies, consists of two salts: ammonium carbonate and ammonium carbamate. $\mathrm{H}_{4} \mathrm{CO}_{2} \mathrm{NH}_{2}(\mathrm{~s})$ (ammonium carbamate) decomposes under heating to $\mathrm{NH}_{3}(\mathrm{~g})$ and $\mathrm{CO}_{2}(\mathrm{~g})$.

$$
\mathrm{NH}_{4} \mathrm{CO}_{2} \mathrm{NH}_{2}(\mathrm{~s}) \rightleftharpoons 2 \mathrm{NH}_{3}(\mathrm{~g})+\mathrm{CO}_{2}(\mathrm{~g})
$$

a) Write the expression for the equilibrium constant for this reaction if no $\mathrm{CO}_{2}$ or $\mathrm{NH}_{3}$ are present from the beginning. Simplify the expression as much as possible.

$$
K=\left(p^{2}\left(\mathrm{NH}_{3}\right) \cdot p\left(\mathrm{CO}_{2}\right)\right) / x\left(\mathrm{NH}_{4} \mathrm{CO}_{2} \mathrm{NH}_{2}\right)=4 p^{3}\left(\mathrm{CO}_{2}\right) \text { or } p^{3}\left(\mathrm{NH}_{3}\right) / 2
$$

b) Use the thermodynamic data given in the following table to calculate $\Delta_{r} H^{\circ}$ for the above reaction. Is the reaction endothermic or exothermic at standard conditions?

| Compound | $\Delta_{f} H^{\circ}[\mathrm{kJ} / \mathrm{mol}]$ |
| :--- | :---: |
| $\mathrm{NH}_{4} \mathrm{CO}_{2} \mathrm{NH}_{2}(\mathrm{~s})$ | -461.9 |
| $\mathrm{NH}_{3}(\mathrm{~g})$ | 45.9 |
| $\mathrm{CO}_{2}(\mathrm{~g})$ | -393.5 |

$\Delta_{\mathrm{r}} H^{\circ}=2 \Delta_{\mathrm{f}} H^{\circ}\left(\mathrm{NH}_{3}(\mathrm{~g})\right)+\Delta_{\mathrm{f}} H^{\circ}\left(\mathrm{CO}_{2}(\mathrm{~g})\right)-\Delta_{\mathrm{f}} H^{\circ}\left(\mathrm{NH}_{4} \mathrm{CO}_{2} \mathrm{NH}_{2}(\mathrm{~s})\right)$
$\Delta_{\mathrm{r}} H^{\circ}=2 \cdot 45.9+(-393.5)-(-461,9)=160,2 \mathrm{~kJ} / \mathrm{mol}$

Answer: $\quad \Delta_{r} H^{\circ}==160,2 \mathrm{~kJ} / \mathrm{mol}$

In an experiment pure $\mathrm{NH}_{4} \mathrm{CO}_{2} \mathrm{NH}_{2}$ and nothing else is in closed vessel. After some time, equilibrium is reached, the temperature being $40^{\circ} \mathrm{C}$

$$
\mathrm{NH}_{4} \mathrm{CO}_{2} \mathrm{NH}_{2}(\mathrm{~s}) \rightleftharpoons 2 \mathrm{NH}_{3}(\mathrm{~g})+\mathrm{CO}_{2}(\mathrm{~g})
$$

The total pressure in the vessel is recorded to 0.327 bar.
c) Calculate the partial pressure of $\mathrm{CO}_{2}$ in vessel.

$$
p(\text { total })=2 \cdot p\left(\mathrm{NH}_{3}\right)+p\left(\mathrm{CO}_{2}\right)=0.327 \mathrm{bar} \Rightarrow p\left(\mathrm{CO}_{2}\right)=0.109 \mathrm{bar}
$$

Answer: $\quad P_{\left(\mathrm{CO}_{2}\right)}=0.109 \mathrm{bar}$
d) Calculate the value of the equilibrium constant, $K$ at $40^{\circ} \mathrm{C}$.
$K=\left(p^{2}\left(\mathrm{NH}_{3}\right) \cdot p\left(\mathrm{CO}_{2}\right)\right) / x\left(\mathrm{NH}_{4} \mathrm{CO}_{2} \mathrm{NH}_{2}\right)=4 p^{3}\left(\mathrm{CO}_{2}\right)=4(0.109)^{3}=0,00515 \mathrm{bar}^{3}$

Answer: $K==0,00515 \mathrm{bar}^{3}$

Originally $2,00 \mathrm{~mol} \mathrm{NH}_{4} \mathrm{CO}_{2} \mathrm{NH}_{2}(\mathrm{~s})$ was placed in the vessel, with the volume of 100 L at $40^{\circ} \mathrm{C}$..
e) Calculate the amount of $\mathrm{NH}_{4} \mathrm{CO}_{2} \mathrm{NH}_{2}($ s $)$ present at equilibrium; assume that the volume of the solid substance can be neglected.
$p\left(\mathrm{CO}_{2}\right)=0.109 \mathrm{bar}, n=\frac{p V}{R T}=\frac{0.109 \cdot 100}{0.08314 \cdot 313}=0.42 \mathrm{~mol}$
$n\left(\mathrm{NH}_{4} \mathrm{CO}_{2} \mathrm{NH}_{2}\right)=2.00 \mathrm{~mol}-0.42 \mathrm{~mol}=1.58 \mathrm{~mol}$

Answer: $\quad n\left(\mathrm{NH}_{4} \mathrm{CO}_{2} \mathrm{NH}_{2}\right)=1.58 \mathrm{~mol}$
$\Delta_{r} H^{\circ}$ for decomposing of $1 \mathrm{~mol} \mathrm{NH}_{4} \mathrm{CO}_{2} \mathrm{NH}_{2}(\mathrm{~s})$ was calculated under point b), if you don't have a result for $\Delta_{r} H^{\circ}$ then use the value $150.0 \mathrm{~kJ} / \mathrm{mol}$. The temperature was now raised to $50^{\circ} \mathrm{C}$.
f) Calculate $K$ at $50^{\circ} \mathrm{C}$, assuming that $\Delta_{r} H^{\circ}$ and $\Delta_{r} S^{\circ}$ is independent of temperature. If you miss parameter values that would have been obtained from previous part you can set these parameters to 1 .
$\ln K=-\frac{\Delta G}{R T}=\frac{-\Delta H}{R T}+\frac{\Delta S}{R}$ valid both at $40^{\circ} \mathrm{C}$ and $50^{\circ} \mathrm{C}$. Subtraction gives:
$\ln \frac{K_{313}}{K_{323}}=\frac{-\Delta H}{R}\left(\frac{1}{313}-\frac{1}{323}\right)=\ln K_{323}+\frac{\Delta H}{R}\left(\frac{1}{313}-\frac{1}{323}\right)=\ln 0.00518+\frac{160200}{8.314}\left(\frac{1}{313}-\frac{1}{323}\right)$

In $K_{323}=-5,263+19268 \cdot(0.0000989)=-3.357 \Rightarrow K_{323}=0.0348 \mathrm{bar}^{3}$

Answer: $K=0.0348 \mathrm{bar}^{3}$

## Problem 2

8 \% of total

| a | b | c | d | e | f | Problem 2 | $\%$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 10 | 10 | 10 | 10 | 10 | 10 |  | 8 |
|  |  |  |  |  |  |  |  |

The oxidation of carbon monoxide to carbon dioxide in the gas phase is assumed to take place in two steps: The oxygen molecule dissociates into oxygen atoms, which then react with carbon monoxide.

$$
\begin{align*}
& \mathrm{CO}_{(g)}+1 / 2 \mathrm{O}_{2(g)} \rightarrow \mathrm{CO}_{(g)}+\mathrm{O}_{(g)}  \tag{1}\\
& \mathrm{CO}_{(g)}+\mathrm{O}_{(g)} \rightarrow \mathrm{CO}_{2(g)} \tag{2}
\end{align*}
$$

The first step (1) is considered to be rate-limiting. The rate of reaction was measured for different partial pressures of CO and $\mathrm{O}_{2}$ at $1250^{\circ} \mathrm{C}$. The values given in the table are the initial partial pressures of CO and $\mathrm{O}_{2}$ and the time (in hours) that it took to lower the CO concentration by 0.1 mbar. Assume that initially there are no other gases present in the reaction vessel.

| Experiment <br> $\#$ | $\mathrm{PO}_{2}$ (bar) | $\mathrm{Pco}($ bar $)$ | $\mathrm{t}(\mathrm{h})$ |
| :---: | :---: | :---: | :---: |
| 1 | 100 | 50 | 21.0 |
| 2 | 200 | 50 | 5.26 |
| 3 | 100 | 100 | 21.1 |

a) Write the rate law for the reaction. Does it agree with the assumption that the first step is rate-limiting?

The reaction time is four times lower when the $\mathrm{O}_{2}$ pressure is doubled => The rate law is second order with respect to $\mathrm{O}_{2}$. The reaction time does not change (significantly) when the CO pressure is doubled => The rate law is zeroth order with respect to CO.

Rate law: $\mathrm{R}=k\left(\mathrm{PO}_{2}\right)^{2}$
Are the rate law in agreement with the assumption that the first step is rate-limiting? XYes $\square$ No

The rate constant of the reaction was measured in experiments at a series of temperatures. The results are given in the table below.

| $\mathrm{T}\left({ }^{\circ} \mathrm{C}\right)$ | $\ln (k)$ |
| :---: | :---: |
| 100 | -90.3 |
| 500 | -48.7 |
| 750 | -39.3 |
| 1000 | -33.5 |
| 1250 | -29.7 |
| 1500 | -26.9 |

b) Use the experimental data to estimate the activation energy of the reaction.

The slope of the linear fit is approximately -29900 and this should be equal to $E_{A} / R$. Therefore, we have $E_{a}=249 \mathrm{~kJ} / \mathrm{mol}$.

Answer: $\quad E_{a}=249 \mathrm{~kJ} / \mathrm{mol}$

Experiments have shown that the oxidation of CO is much faster on some metal surfaces. Such catalysis has been used in catalytic converters for car exhaust. The proposed reaction mechanism is that (1) the two gas molecules are adsorbed on the metal surface, where (2) $\mathrm{O}_{2}$ is dissociated and (3) $\mathrm{CO}_{2}$ formed. The schematic figure below (based on data from Ertl, 1983) shows a schematic energy diagram for the oxidation of CO on a $\mathrm{Pt}(111)$ surface.

c) Which is the rate-limiting step in the catalysed reaction mechanism?

The second step, $\mathrm{CO}_{\text {ads }}+\mathrm{O}_{\text {ads }} \rightarrow \mathrm{CO}_{\text {2ads }}$, may be assumed to be rate-limiting as it has the highest activation energy; $\mathrm{E}_{\mathrm{A}}=105 \mathrm{~kJ} / \mathrm{mol}$.
d) Calculate the rate constant of the catalysed reaction at $100^{\circ} \mathrm{C}$ assuming that the preexponential factor is $10^{14} \mathrm{~s}^{-1}$.

If $A=10^{14} \mathrm{~s}^{-1}$ and $E_{a}=105 \mathrm{~kJ} / \mathrm{mol}$, then $k_{c a t}=A \exp \left(-E_{A} / R T\right)=0.198 \mathrm{~s}^{-1}$ at $100^{\circ} \mathrm{C}$.

Answer: $\quad k_{c a t}=0.198 \mathrm{~s}^{-1}$
e) How much faster is the catalysed reaction at $100^{\circ} \mathrm{C}$ ?

At $100^{\circ} \mathrm{C}$ we have
$\ln (k)=-90.3=>\log _{10}(k)=-39.2$ and $\ln \left(k_{\text {cat }}\right)=-1.6 \Rightarrow \log _{10}\left(k_{\text {cat }}\right)=-0.70$.

Therefore, the catalysed reaction is about $10^{38.5}$ faster than the uncatalysed reaction.

Answer: $10^{38.5}=3,16 \cdot 10^{38}$ times faster

## Problem 3

## 8 \% of total

| a | b | c | d | e | Problem 3 | $x \%$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 10 | 10 | 10 | 10 | 10 | 50 | 8 |
|  |  |  |  |  |  |  |

Global warming and fossil fuel depletion increasingly place the development of sustainable energy systems at the top of political agendas around the world. Major investments in new energy technologies and systems to improve energy efficiency and reduce greenhouse gas emissions will continue to grow the coming decades. Some of the suggested technologies for energy production and energy storage are based on electrochemistry, i.e.: batteries, fuel cells, electrochemical solar cells, supercapacitors.

One promising alternative is a metal-air battery, i.e.: a hybride fuel cell.

Consider an aluminum-air battery, which is a light and very promising battery for carbonfree vehicles.
a) The standard electrode reduction potential $E^{0}$ for aluminum is -1.66 V and for oxygen in an acidic water solution it is 1.23 V . What are the corresponding reactions at the anode and cathode respectively in acidic environment? What is the total cell reaction in an acidic environment? Note: The figure above shows the cell in basic environment.

Anode reaction: $\mathrm{Al}(\mathrm{s}) \rightleftharpoons \mathrm{Al}^{3+}++3 \mathrm{e}^{-}$

Cathode reaction: $\mathrm{O}_{2}(\mathrm{~g})+4 \mathrm{H}^{+}+4 \mathrm{e}^{-} \rightleftharpoons 2 \mathrm{H}_{2} \mathrm{O}(\mathrm{I})$

Cell reaction: $4 \mathrm{Al}(\mathrm{s})+3 \mathrm{O}_{2}(\mathrm{~g})+12 \mathrm{H}^{+} \rightleftharpoons 4 \mathrm{Al}^{3+}+6 \mathrm{H}_{2} \mathrm{O}(\mathrm{I})$
(Total reaction $=3$ Cathode -4 Anode)
b) Calculate the thermodynamic standard cell potential in acidic environment.
$\mathrm{E}^{0}{ }_{\text {cell }}=1.23 \mathrm{~V}-(-1.66) \mathrm{V}=2.89 \mathrm{~V}$

Answer: $\quad E^{\circ}{ }^{c}$ cell $=2.89 \mathrm{~V}$
c) In practice the aluminum-air battery is often build with a basic electrolyte (e.g. KOH ) in which solid aluminum hydroxide is formed and the reduction of oxygen occurs in basic water solution. What are the corresponding reactions at the anode and cathode respectively? What is the total cell reaction in a basic environment?

In basic environment (all half-reactions written as reductions):
The anode reaction is coupled the formation of aluminum hydroxide:
(1)
$\mathrm{Al}^{3+}+3 \mathrm{e}^{-} \rightleftharpoons \mathrm{Al}(\mathrm{s})$
$\mathrm{E}^{0}{ }_{1}=-1.66 \mathrm{~V}$
(2)
$\mathrm{Al}(\mathrm{OH})_{3}(\mathrm{~s}) \rightleftharpoons \mathrm{Al}^{3+}+3 \mathrm{OH}^{-}$
$\mathrm{K}_{2}=\mathrm{K}_{\mathrm{sp}}=1.3 \cdot 10^{-33}$
$(3)=(1)+(2) \quad \mathrm{Al}(\mathbf{O H})_{3}(\mathbf{s})+3 \mathrm{e}^{-} \rightleftharpoons \mathrm{Al}(\mathbf{s})+3 \mathrm{OH}^{-}$

Cathode reaction in basic solution:

$$
\begin{equation*}
\mathrm{O}_{2}(\mathrm{~g})+4 \mathrm{H}^{+}+4 \mathrm{e}^{-} \rightleftharpoons 2 \mathrm{H}_{2} \mathrm{O}(\mathrm{I}) \quad \mathrm{E}^{0} 4=+1.23 \mathrm{~V} \tag{4}
\end{equation*}
$$

(5)
$\mathrm{H}_{2} \mathrm{O}(\mathrm{I}) \rightleftharpoons \mathrm{H}^{+}+\mathrm{OH}^{-}$
$\mathrm{K}_{5}=\mathrm{K}_{\mathrm{w}}=1.0 \cdot 10^{-14}$
$(6)=(4)+4 \cdot(5)$
$\mathrm{O}_{2}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{I})+4 \mathrm{e}^{-} \rightleftharpoons 4 \mathrm{OH}^{-}$
The total cell reaction $=3$ Cathode -4 Anode $=3(6)-4(3)$ :

$$
4 \mathrm{Al}(\mathrm{~s})+3 \mathrm{O}_{2}(\mathrm{~g})+6 \mathrm{H}_{2} \mathrm{O}(\mathrm{I}) \rightleftharpoons 4 \mathrm{Al}(\mathrm{OH})_{3}(\mathrm{~s})
$$

Answers: Anode reaction: $\mathrm{Al}(\mathrm{s})+3 \mathrm{OH}^{-} \rightleftharpoons \mathrm{Al}(\mathrm{OH})_{3}(\mathrm{~s})+3 \mathrm{e}^{-}$
Cathode reaction: $\mathrm{O}_{2}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{I})+4 \mathrm{e}^{-} \rightleftharpoons 4 \mathrm{OH}^{-}$
Total reaction: $4 \mathrm{Al}(\mathrm{s})+3 \mathrm{O}_{2}(\mathrm{~g})+6 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons 4 \mathrm{Al}(\mathrm{OH})_{3}(\mathrm{~s})$
d) Calculate the thermodynamic standard cell potential in a basic environment at 298K.
Hint: Coupled reactions occur at both electrodes which affect the cell potentials. The solubility product of aluminum hydroxide is $K_{s p}=1.3 \cdot 10^{-33}$ and water autoprotolysis ionization constant is $K_{w}=1.0 \cdot 10^{-14}$.

In general:

$$
\begin{aligned}
& \Delta \mathrm{G}^{0}=-\mathrm{RT} \operatorname{lnK}=-\mathrm{nFE}^{0} \\
& \mathrm{E}^{0}=\mathrm{RT} / \mathrm{nF} \ln \mathrm{~K}
\end{aligned}
$$

For the coupled anode reaction (see answer (c))

$$
\ln K_{3}=\ln \left(K_{1} K_{2}\right)=\ln K_{1}+\ln K_{2}
$$

and thus

$$
\begin{aligned}
\mathrm{E}_{3}{ }_{3} & =\mathrm{RT} / \mathrm{nF} \ln \mathrm{~K}_{1}+\mathrm{RT} / \mathrm{nF} \operatorname{lnK} K_{2}=\mathrm{E}^{0}+\mathrm{RT} / \mathrm{nF} \ln \mathrm{~K}_{\text {sp }}= \\
& =-1.66 \mathrm{~V}+8.314 \cdot 298 /(3 \cdot 96485) \ln \left(1.3 \cdot 10^{-33}\right) \mathrm{V}= \\
& =-1.66 \mathrm{~V}-0.65 \mathrm{~V}=-2.31 \mathrm{~V}
\end{aligned}
$$

In similar way for the cathode reaction in basic environment

$$
\ln K_{6}=\ln \left(K_{4} K_{5}{ }^{4}\right)=\ln K_{4}+4 \ln K_{5}
$$

and

$$
\begin{aligned}
\mathrm{E}^{0} 6 & =\mathrm{RT} / \mathrm{nF} \operatorname{lnK} K_{3}+4 \mathrm{RT} / \mathrm{nF} \ln \mathrm{~K}_{5}=\mathrm{E}_{3}{ }_{3}+4 \mathrm{RT} / \mathrm{nF} \ln \mathrm{~K}_{\mathrm{w}}= \\
& =1.23 \mathrm{~V}+4 \cdot 8.314 \cdot 298 /(4 \cdot 96485) \ln \left(1.0 \cdot 10^{-14}\right) \mathrm{V}= \\
& =1.23 \mathrm{~V}-0.83 \mathrm{~V}=0.40 \mathrm{~V}
\end{aligned}
$$

Finally the standard cell potential in basic environment:

$$
\mathrm{E}^{0} \text { cell }=\mathrm{E}_{6}^{0}-\mathrm{E}_{3}^{0_{3}}=0.40 \mathrm{~V}-(-2.31 \mathrm{~V})=2.71 \mathrm{~V}
$$

Answer: $\quad E^{\circ}{ }_{\text {cell }}=2.71 \mathrm{~V}$
e) Is the real potential of the cell in basic environment higher or lower than the thermodynamic standard cell potential? Motivate your answer by showing the calculations in basic environment

The total cell reaction in basic environment is

$$
4 \mathrm{Al}(\mathrm{~s})+3 \mathrm{O}_{2}(\mathrm{~g})+6 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons 4 \mathrm{Al}(\mathrm{OH})_{3}(\mathrm{~s})
$$

The real cell potential is slightly lower than the standard potential since in air the oxygen partial pressure pushing the reaction (Le Chatelier's principle) is lower than the standard 1 bar. In air po2 $\approx 0.2$ bar.

From Nernst equation:

$$
\begin{aligned}
\mathrm{E}_{\text {cell }} & =\mathrm{E}^{0} \text { cell }-\mathrm{RT} / \mathrm{nF} \ln \mathrm{Q}= \\
& =\mathrm{E}^{0} \text { cell }-\mathrm{RT} / 12 \mathrm{~F} \ln \left(\left\{\mathrm{Al}(\mathrm{OH})_{3}(\mathrm{~s})\right\}^{4} /\{\mathrm{Al}(\mathrm{~s})\}^{4}\left\{\mathrm{poo}^{3}\right\}^{3}\left\{\mathrm{H}_{2} \mathrm{O}(\mathrm{I})\right\}^{6}\right) \\
& =\mathrm{E}^{0} \text { cell }-\mathrm{RT} / 12 \mathrm{~F} \ln \left(1 /\left(\mathrm{poz}_{2} / \mathrm{p}^{0}\right)^{3}\right) \\
& =\mathrm{E}_{\text {cell }}^{0}+3 \mathrm{RT} / 12 \mathrm{~F} \ln \left(\mathrm{poz}_{2} / 1 \mathrm{bar}\right) \\
& =\mathrm{E}^{0} \text { cell }+\mathrm{RT} / 4 \mathrm{~F} \ln (0.2) \\
& =2.71 \mathrm{~V}-0.01 \mathrm{~V}=2.70 \mathrm{~V}
\end{aligned}
$$

where the activity of pure condensed matter is one, e.g. $\{\mathrm{Al}(\mathrm{s})\}=1$.

## Problem 4

## $9 \%$ of total

| a | b | c | d | e | f | g | h | Problem 4 | $\mathrm{x} \%$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 80 | 9 |
|  |  |  |  |  |  |  |  |  |  |

Pure iron metal melts at 1811 K . Between room temperature and its melting point, iron metal can exist in different allotropic or crystalline forms. From room temperature to 1185 K , the crystal structure of iron metal exists as a body-centered cubic (bcc) lattice known as $\alpha$-iron. Use the following data for this task: $\mathrm{M}(\mathrm{Fe})=55.847 \mathrm{~g} / \mathrm{mol}, \mathrm{M}(\mathrm{C})=12.011 \mathrm{~g} / \mathrm{mol}$, $\mathrm{N}_{\mathrm{A}}=6.02214 \times 10^{23} / \mathrm{mol}$
a) Copy the general cube below and draw a sketch showing how atoms are distributed in a bcc lattice.

Several sketches are correct, e.g.

c) the density of pure iron metal is $7.874 \mathrm{~g} / \mathrm{cm}^{3}$ at 293 K . Calculate the atomic radius of iron (expressed in cm ).

Two atoms of iron has a mass of $2 \times \mathrm{M}(\mathrm{Fe})$. The density is defined as $\mathrm{d}=$ mass/volume, where volume is $\mathrm{V}=a^{3}$ where $a$ is the dimension of the sides of the cube. Finally, the radius of the iron atom ( $R$ ) is found to be 4 times the diagonal of the cube, which is given as $\sqrt{3} a$ (see figure below). Using this information,
$V=\left(2 \cdot 55.847 \mathrm{~g} / \mathrm{mol} / 6.0221410^{23} 1 / \mathrm{mol}\right) / 7.874 \mathrm{~g} / \mathrm{cm}^{3}=2.35610^{-23} \mathrm{~cm}^{3}$,
which gives $\mathrm{a}=2.86710^{-8} \mathrm{~cm}$, and then $\mathrm{R}=\sqrt{3} a / 4=1.24110^{-8} \mathrm{~cm}$.

Answer: $\quad r_{F e}=1.24110^{-8} \mathrm{~cm}$

When heating iron from room temperature, a transition to a face-centered cubic (fcc) form, called $\gamma$-iron, takes place at 1185 K .
d) Copy the general cube below and draw a sketch showing how atoms are distributed in a fcc lattice.

Several sketches are correct, e.g.

r
e) How many atoms of iron are there per unit cell in a fcc cell?

4 atoms ( $6 \times 1 / 2$ on each side, and $8 \times 1 / 8$ per corner)
f) Calculate the density of $\gamma$-iron (expressed in $\mathrm{g} / \mathrm{cm}^{3}$ ). Note: Ignore any small effect due to the thermal expansion of the metal.

From the radius $R=1.24110^{-8} \mathrm{~cm}$ the volume of the fcc cell is given by
$V=a^{3}=(4 R / \sqrt{ } 2)^{3}=4.32710^{-23} \mathrm{~cm}^{3}$ (see figure below).
With 4 atoms per cell, the density becomes $d=\left(4 \cdot \mathrm{M}(\mathrm{Fe}) / \mathrm{N}_{\mathrm{A}}\right) / \mathrm{V}=8.573 \mathrm{~g} / \mathrm{cm}^{3}$.

Answer: Density of $\gamma$-iron $=8.573 \mathrm{~g} / \mathrm{cm}^{-3}$

Steel is an alloy of iron and carbon in which some of the interstitial spaces ("holes") of the crystal lattice (iron) are occupied by small atoms (carbon). The carbon content in steel typically ranges from $0.1 \%$ to $4.0 \%$. In a blast-furnace, the melting of iron is facilitated when it contains $4.3 \%$ of carbon by mass. If this mixture is cooled too rapidly the carbon atoms remain dispersed within the $\alpha$-iron phase. This new solid, called martensite, is extremely hard and brittle. The size of the unit cell of martensite is the same as that of $\alpha$ iron ( $b c c$ ). Assume that the carbon atoms are evenly distributed in the iron structure
g) Calculate the average number of carbon atoms per unit cell of $\alpha$-iron in martensite containing 4.3 \% C by mass.

100 g martensite contains 4.3 g C and 95.7 g Fe ,
which corresponds to 0.36 mol C and 1.71 mol Fe ,
and thus the ratio $\mathrm{Fe}: \mathrm{C}$ is $4.8: 1$, or 0.21 C -atoms per Fe -atom.
Since there are 2 Fe atoms per bbc cell, there are on average 0.42 C -atoms per unit cell.

Answer: Average number of carbon atoms per unit cell $=0.42$
h) Calculate the density (expressed in $\mathrm{g} / \mathrm{cm}^{3}$ ) of this material.

The total mass of material per bcc cell in martensite is
$(2 \cdot \mathrm{M}(\mathrm{Fe})+0.42 \mathrm{M}(\mathrm{C})) / \mathrm{N}_{\mathrm{A}}=$
$=(2 \cdot 55.847 \mathrm{~g} / \mathrm{mol}+0.42 \cdot 12.011 \mathrm{~g} / \mathrm{mol}) / 6.0221410^{23} 1 / \mathrm{mol}=$
$=1.938510^{-22} \mathrm{~g}$ material.

The density of martensite is $\mathrm{d}=\mathrm{m} / \mathrm{V}=1.938510^{-22} \mathrm{~g} / 2.35610^{-23} \mathrm{~cm}^{3}=$ $=8.228 \mathrm{~g} / \mathrm{cm}^{3}$.

Answer: Density $=8.228 \mathrm{~g} / \mathrm{cm}^{3}$.

## Problem 5 <br> $9 \%$ of total

| $a$ | $b$ | $c$ | $d$ | $e$ | $f$ | $g$ | $h$ | Problem 5 | $\%$ |

The most recent use of chemical warfare agents, CWA, was in Syria this year. Methods for the destruction of CWAs exist and involves strong oxidants. This problem will deal with some aspects of a new potential method for trapping CWAs by means of coordination cages, using only mild conditions as developed by Michael D. Ward and published 2016. A coordination cage is a supramolecular assembly of metal ions and ligands and have shown to trap other molecules within the available space in the

A coordination cage trapping a guest molecule. cage, e.g. CWAs.
a) If two different ligands $A$ and $B$, three of each kind, coordinates in an octahedral geometry, then what are the possible different isomers that exist? Use the following template and write $A$ and $B$ in the circles for all isomers.

b) Sarin is one of the most common chemical warfare agents. Write its full Lewis structure and state the geometry at the phosphorus center.

A sarin molecule

Geometry at the phosphorous center: Tetrahedral
c) The crystal field-splitting diagram for an octahedral complex has two sets of energy levels, which $d$-orbitals corresponds to the different energy levels? Write the correct $d$-orbitals on the lines in the diagram.

d) The coordination cage consists of $8 \mathrm{Co}^{2+}$ ions and 12 ligands. Each metal ion center is an octahedral coordination complex. If the ligands are high field, to the far right in the spectrochemical series, then what is the electron configuration? Draw arrows to denote an electron and its spin in the splitting diagram in this case. Is the complex high-spin or low-spin?

e) How many electrons does each $\mathrm{Co}^{2+}$ center have in its valence shell? Mark with a cross in the correct box.
i) $\square 16$
ii) $\square 17$
iii) $\square 18$
iv) $\boxtimes 19$
v) $\square 20$
f) These cages can also be constructed with $\mathrm{Cd}^{2+}$ ions. Mark the correct property for these coordination centers.
i) $\square$ High-spin
ii) $\square$ Low-spin
iii) $\boxtimes$ Neither of i) and ii

The equilibrium reactions that describes how a coordination host cage, $\mathrm{Co}-\mathrm{H}$, takes up DMMP molecules can be written as:

$$
\begin{array}{ll}
\mathrm{Co}-\mathrm{H}+\mathrm{DMMP} \rightleftharpoons \mathrm{Co}-\mathrm{H}-\mathrm{DMMP} & \mathrm{~K}_{1} \\
\mathrm{Co}-\mathrm{H}-\mathrm{DMMP}+\mathrm{DMMP} \rightleftharpoons \mathrm{Co}-\mathrm{H}-(\mathrm{DMMP})_{2} & K_{2} \tag{2}
\end{array}
$$

Where $\mathrm{Co}-\mathrm{H}: \quad$ Host cage with Co metal ions.
K: Equilibrium constant.
DMMP: Dimethyl methylphosphonate. A model substance for a CWA

molecule.
A DMMP molecule
g) In acetonitrile solution there is only possible for the cage to take up one DMMP molecule. The equilibrium constant at 298 K is $K_{1}=4.0 \mathrm{M}^{-1}$. Calculate the molar concentration of free DMMP molecules in a solution with the following initial concentrations $[\mathrm{Co}-\mathrm{H}]_{\text {initial }}=0,100 \mathrm{M}$ and $[\mathrm{DMMP}]_{\text {initial }}=1.00 \cdot 10^{-6} \mathrm{M}$.

$$
\begin{array}{lll} 
& \mathrm{Co}-\mathrm{H}+\underset{\mathrm{DMMP}}{ }+ & \rightleftharpoons \\
0,100-x 1,00 \cdot 10^{-6}-\mathrm{x}
\end{array} \quad \begin{aligned}
& \mathrm{Co}-\mathrm{H}-\mathrm{DMMP} \\
& K_{1}=\frac{x}{(0.100-x)\left(1.00 \cdot 10^{-6}-x\right)}=4.0 \mathrm{M}^{-1}
\end{aligned}
$$

Assume $x \ll 0,100$ then
$K_{1}=\frac{x}{(0.100)\left(1.00 \cdot 10^{-6}-x\right)}=4.0 \mathrm{M}^{-1}$
$1.4 x=4.0 \cdot 10^{-7} \Rightarrow x=2.86 \cdot 10^{-7} \mathrm{M}$
$[\mathrm{DMMP}]=\left(1.00 \cdot 10^{-6}-2.86 \cdot 10^{-7}\right)=7.14 \cdot 10^{-7} \mathrm{M}$
$[D M M P]=7.1 \cdot 10^{-7} \mathrm{M}$

Answer: [DMMP] = 7,1•10-7 M
h) In water the Co-H cage can take up two DMMP molecule. The equilibrium constants at 298 K is $K_{1}=K_{2}=7.0 \mathrm{M}^{-1}$. W. An aqueous solution can be purified from DMMP by extraction, where $\mathrm{Co}-\mathrm{H}-\mathrm{DMMP}$ and $\mathrm{Co}-\mathrm{H}-(\mathrm{DMMP})_{2}$ are selectively and repeatedly removed from the solution. Calculate the percentage of DMMP molecules that have been removed during the first purification step when $[\mathrm{Co}-\mathrm{H}]$ initial $=0.100 \mathrm{M}$ and $[D M M P]_{\text {jititial }}=1.00 \cdot 10^{-8} \mathrm{M}$.
$[D M M P]+[\mathrm{Co}-\mathrm{H}-\mathrm{DMMP}]+2\left[\mathrm{Co}-\mathrm{H}-(\mathrm{DMMP})_{2}\right]=[\mathrm{DMMP}]_{\text {inital }}=1.0 \cdot 10^{-8} \mathrm{M}$
Assume that $[\mathrm{Co}-\mathrm{H}]_{\text {initial }}=[\mathrm{Co}-\mathrm{H}]=0.100 \mathrm{M}$

$$
\begin{aligned}
& \frac{[\mathrm{Co}-\mathrm{H}-\mathrm{DMMP}]}{[\mathrm{Co}-\mathrm{H}][\mathrm{DMMP}]}=K_{1}=7.0 \mathrm{M}^{-1} \Rightarrow[\mathrm{Co}-\mathrm{H}-\mathrm{DMMP}]=7.0[\mathrm{Co}-\mathrm{H}][\mathrm{DMMP}] \\
& \quad=7.0 \cdot 0,100 \cdot[\mathrm{DMMP}]=0,7[\mathrm{DMMP}] \Rightarrow \\
& \quad[\mathrm{Co}-\mathrm{H}-\mathrm{DMMP}]=0,7[\mathrm{DMMP}] \\
& \frac{\left[\mathrm{Co}-\mathrm{H}-(\mathrm{DMMP})_{2}\right]}{[\mathrm{Co}-\mathrm{H}-\mathrm{DMMP}][\mathrm{DMMP}]}=K_{2}=7,0 \mathrm{M}^{-1} \quad \Rightarrow
\end{aligned}
$$

$\left[\mathrm{Co}-\mathrm{H}-(\mathrm{DMMP})_{2}\right]=7.0[\mathrm{Co}-\mathrm{H}-\mathrm{DMMP}][\mathrm{DMMP}]$
Use equation (2) $\Rightarrow\left[\mathrm{Co}-\mathrm{H}-(\mathrm{DMMP})_{2}\right]=7.0 \cdot 0.7[\mathrm{DMMP}][\mathrm{DMMP}] \Rightarrow$

$$
\begin{equation*}
\left[\mathrm{Co}-\mathrm{H}-(\mathrm{DMMP})_{2}\right]=4.9[\mathrm{DMMP}]^{2} \tag{3}
\end{equation*}
$$

Equations (2) and (3) in (1):
$[\mathrm{DMMP}]+0.7[\mathrm{DMMP}]+2 \cdot 4.9[\mathrm{DMMP}]^{2}=1.00 \cdot 10^{-8} \Rightarrow$
$1.7[\mathrm{DMMP}]+9.8[\mathrm{DMMP}]^{2}=1.00 \cdot 10^{-8} \Rightarrow$
$[\mathrm{DMMP}](1.7+9.8[\mathrm{DMMP}])=1.00 \cdot 10^{-8}$
Assume that $9.8[\mathrm{DMMP}]) \ll 1.7 \Rightarrow[D M M P]=\frac{1.00 \cdot 10^{-8}}{1.7}$
DMMP removed $=\frac{[\mathrm{DMMP}]_{\text {initial }}-[\mathrm{DMMP}]}{[\mathrm{DMMP}]_{\text {initial }}}=$
$=\frac{1.00 \cdot 10^{-8}-\frac{1.00 \cdot 10^{-8}}{1.7}}{1.00 \cdot 10^{-8}}=41,2 \%$

Percentage of DMMP removed: 41,2\%

## Problem 6 <br> $9 \%$ of total

| a | b | c | d | e | f | g | Problem 6 | $\%$ |

| 10 | 10 | 10 | 10 | 10 | 10 | 10 | 70 | 9 |
|  |  |  |  |  |  |  |  |  |

Carbonyl compounds are often in keto-enol equilibrium. The enol form is very important for carbonyl condensation reactions.

Ethyl acetoacetate and 2,4-pentanedione keto-enol tautomerism was studied with ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR.

In theory, three different enol tautomers (B-D) can exist in solution (Benzene) for the ethyl acetoacetate. The CD is time-averaged structure that is commonly observed in NMR timescale.

${ }^{1} \mathrm{H}$ NMR spectrum of ethyl acetoacetate in $C_{6} D_{6}$ (residual signal 7.16 ppm ). The spectrum is integrated with values above the integral curves.

Corresponding situation can prevail for 2,4-pentanedione. The ${ }^{13} \mathrm{C}$ spectra have been measured in $\mathrm{CD}_{3} \mathrm{CN}$.

I: proton coupled and II: proton decoupled ${ }^{13} \mathrm{C}$ NMR spectrum of 2,4-pentanedione in $\mathrm{CD}_{3} \mathrm{CN}$ (118.26 and 1.32 ppm)

## Characteristic ${ }^{\mathbf{1}} \mathbf{H}$ NMR Chemical Shifts

| Type of Hydrogen $(\mathbf{R}=\text { Alkyl }, \mathbf{A r}=\mathbf{A r y l})$ | Chemical Shift (ppm) | Type of Hydrogen ( $\mathrm{R}=$ Alkyl, $\mathrm{Ar}=$ Aryl) | Chemical Shif (ppm) |

| $\mathrm{RCH}_{2} \mathrm{OR}$ | $65-70$ |  |  |

a) How many ${ }^{1} \mathrm{H}$ NMR signals would ethyl acetoacetate tautomers $\mathbf{A}, \mathbf{B}, \mathbf{C}$ and $\mathbf{D}$ produce (ignore multiplicities)?

A: 4
B: 5
C: 5
D: 5
b) How will the time averaging (CD) change the number of signals in the proton spectrum?

5 signals
c) How many ${ }^{13} \mathrm{C}$ NMR signals would 2,4-pentanedione tautomers $\mathbf{A}, \mathbf{B}, \mathbf{C}$ and $\mathbf{D}$ produce.

A: 3
B: 5
C: 5
D: 5
d) How will the time averaging (CD) change the number of signals in the carbon spectrum?

3 signals
e) Interpret what tautomers (A-D) can be identified in the ${ }^{1} \mathrm{H}$ NMR spectrum. (or possibly mixtures of minor and major). Identify characteristic signals.

Minor tautomer(s): CD. Characterstic signals:12.70, 5.00 and 1.7ppm
Major tautomer(s): A. Characterstic signals 1.90 and 3.2 ppm [Ethyl ester: 1.05 and 4.02ppm]
f) Interpret what tautomers (A-D) can be identified in the ${ }^{13} \mathrm{C}$ NMR spectra above. (or possibly mixtures). Identify characteristic signals.

Again $\mathbf{A}$ and $\mathbf{C D}$ is considered.
The six signals arises from the tautomers.
Ketone 205 ppm belongs to A, while averaged carbonyl gives 192 ppm.
100 ppm is $\mathbf{C D}$ enol methylene, while 58 ppm CH 2 of $\mathbf{A}$.

Disproportionation is a process where both oxidation and reduction takes place (bimolecularly) for single molecule yielding two products. In the case of (aromatic)aldehydes the process give alcohols and acid.

Question. Salicylaldehyde was stored extended periods of time in toluene. After isolation of compounds from the mixture four different IR spectra (1-4) could be recorded. Identify them i.e. find characteristic signals for each compound, by using the IR absortion frequencies tables.

| N-O | stretch | $1515-1560 \& 1345-1385$ | strong, two bands |

IR Absorption Frequencies of Functional Groups Containing a Carbonyl ( $\mathbf{C = O}$ )

g) Identify the compounds and explain briefly your reasoning. (Remember that absolute IR stretching values differ to some extent from the tabularised ones due to interaction of functional groups

The idea is to find characteristic signals that are aldehyde, OH and COOH stretching. One must then rationalize which spectra contain them and which not. The phenol signals makes the characterization more challenging while the OH hydrogen bonds effect on the hydrogen bond acceptor signals.

Spectrum 1: Spectrum shows strong signal at ca. $1700 \mathrm{~cm}^{-1}$. Compared to spectrum 2 there is one characteristic OH signal at $3200 \mathrm{~cm}^{-1}$. This is salicylic acid spectrum.

Spectrum 2: Spectrum shows also strong signal at ca. $1700 \mathrm{~cm}^{-1}$. Less OH than above. This is salicylic aldehyde spectrum. (The hydrogen bonding shifts aldehyde vibration to unusually low frequency.)

Spectrum 3: No strong CO (ca. $1700 \mathrm{~cm}^{-1}$ ) absorption, but broad signals in $3200-3600 \mathrm{~cm}^{-1}$. Compound is salicyl alcohol.

Spectrum 4: No broad signals above $3000 \mathrm{~cm}^{-1}$ that are typical for OH , neither no strong $\mathrm{C}=\mathrm{O}$ stretching signal for. This compound is toluene.

## Problem 7

Pfizer's cholesterol-lowering drug Lipitor has been the best-selling pharmaceutical in the world. The active compound in Lipitor, atorvastatin, belongs to the drug class of statins. Atorvastatin acts by inhibiting a HMG-coA reductase in the liver which is involved in the production of cholesterol.

The first steps of a multi-stage synthesis of Lipitor are shown below.
Given in the boxes are the most characteristic IR stretching frequencies of the intermediates in the synthesis. No stretches due to any $\mathrm{C}-\mathrm{C}$ or $\mathrm{C}-\mathrm{H}$ bonds are included; stretching frequencies due to single bonds other than bonds to hydrogen do not show up in the range listed. You are not expected to know these stretching frequencies, but through careful reasoning, you should be able to use them to help work out the structures of the unknowns.

Note that not all the by-products are shown in the reaction schemes below

a) Give the structures for the compounds $\mathbf{B}$ to $\mathbf{G}$.

b) Over the course of the whole question, complete the table of IR absorptions (in the answer sheet) found in compounds $\mathbf{A}$ to $\mathbf{M}$.

Answer:

| absorption <br> $/ \mathrm{cm}^{-1}$ | $\sim 3300$ <br> (broad) | $\mathbf{1 7 7 5}$ | $2250-2275$ | 3374 | $1700-1740$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| bond | $\mathbf{O - H}$ | C=O in a <br> small ring | $\mathbf{C \equiv N}$ | $\mathrm{N}-\mathrm{H}$ | $\mathbf{C = O}$ |

Ester $\mathbf{H}$ is deprotonated by strong bases to give the reactive carbon nucleophile, anion I. The $R$ group in the structure is an alkyl chain which remains unchanged throughout the entire synthesis.

c) Draw the structure for the anion $I$.

## Anion I

2 marks
or

(1 mark for this alternative)

The synthesis continues as shown below:

d) Give the structures for the compounds $\mathbf{J}, \mathbf{K}$ and $\mathbf{L}$.

In a separate branch of the synthesis, $\mathbf{N}$ reacts with phenylamine to give compound $\mathbf{O}$.
This compound reacts with benzaldehyde in an aldol condensation to give compound $\mathbf{P}$. $\mathbf{P}$ then reacts further with fluorobenzaldehyde in the presence of a catalyst to give compound Q.

e) give the structures of phenylamine and 4-fluorobenzaldehyde.

phenylamine

4-fluorobenzaldehyde

## The end of the problem set
